### CompTIA DataSys+ Certification Exam Sample Questions (Q92-Q97):

#### NEW QUESTION # 92

Gary is logging into a system and is providing his fingerprint to gain access. What step of the IAM process is he performing?

- A. Accounting
- B. Identification
- C. Authentication
- D. Authorization

**Answer: C**

#### NEW QUESTION # 93

A database system crashed during a routine migration process. Which of the following should the systems administrator refer to for guidance in this situation?

- A. The access control policy
- B. The data retention policy
- C. The continuity of operations policy
- D. The database compliance policy

**Answer: C**

Explanation:

The continuity of operations policy provides guidelines and procedures for maintaining or restoring essential functions during and after disruptions like a database crash.

#### NEW QUESTION # 94

A DBA is reviewing the following logs to determine the current data backup plan for a primary data server:

□ Which of the following best describes this backup plan?

- A. Daily full
- B. Weekly full, daily incremental
- C. Monthly full, daily differential
- D. Daily differential

**Answer: B**

Explanation:

The backup plan that best describes the logs is weekly full, daily incremental. This means that a full backup of the entire database is performed once a week, and then only the changes made since the last backup are backed up every day. This can be inferred from the logs by looking at the size and duration of the backups. The full backups are larger and take longer than the incremental backups, and they occur every seven days. The other backup plans do not match the pattern of the logs.

#### NEW QUESTION # 95

Which of the following is a reason to create a stored procedure?

- A. To bypass case sensitivity requirements
- B. To improve performance

- C. To minimize storage space
- D. To give control of the query logic to the user

**Answer: B**

Explanation:

A reason to create a stored procedure is to improve performance. A stored procedure is a set of SQL statements or commands that are stored and compiled in the database server, and can be executed by name or by a trigger. A stored procedure can improve performance by reducing the network traffic between the client and the server, as only the name or the parameters of the stored procedure need to be sent, rather than the entire SQL code. A stored procedure can also improve performance by reusing the same execution plan, as the stored procedure is compiled only once and cached in the server memory. The other options are either not true or not relevant for this purpose. For example, a stored procedure does not necessarily minimize storage space, as it still occupies space in the database server; a stored procedure does not bypass case sensitivity requirements, as it still follows the rules of the database system; a stored procedure does not give control of the query logic to the user, as it is defined and maintained by the database administrator or developer. #### NEW QUESTION # 96

A developer is designing a table that does not have repeated values. Which of the following indexes should the developer use to prevent duplicate values from being inserted?

- A. Composite
- **B. Unique**
- C. Implicit
- D. Single column

**Answer: B**

Explanation:

The index that the developer should use to prevent duplicate values from being inserted is unique. A unique index is a type of index that enforces the uniqueness of the values in one or more columns of a table. A unique index ensures that no two rows in the table have the same value or combination of values in the indexed columns. A unique index helps to maintain data integrity and avoid data duplication or inconsistency. The other options are either not related or not effective for this purpose. For example, a single column index is a type of index that involves only one column of a table, but it does not prevent duplicate values unless it is also unique; an implicit index is a type of index that is automatically created by the database system when a constraint or a primary key is defined on a column or columns of a table, but it does not prevent duplicate values unless it is also unique; a composite index is a type of index that involves two or more columns of a table, but it does not prevent duplicate values unless it is also unique.
