NEW QUESTION # 327

What is a consideration when implementing an existing customer-managed VDS on a VxRail cluster?

- A. Requires multiple switches to share each distributed port group.
- B. Supports only two NIC uplinks.
- C. Requires each LAG uplink to exist in the vCenter before implementing.
- D. Supports only four NIC uplinks.

Answer: C

Explanation:

Utilizing a customer-managed Virtual Distributed Switch (VDS) allows enterprise organizations to pre-configure network settings, security policies, and custom port groups within their external vCenter before initiating the VxRail Deployment Wizard. When choosing this deployment pathway, particularly when Link Aggregation Control Protocol (LACP) is selected for network redundancy and load balancing, specific sequencing prerequisites must be followed.

If the architecture dictates the use of an LACP configuration to bundle physical network adapters, each Link Aggregation Group (LAG) uplink structure must be manually created and exist within the customer-managed VDS inside vCenter prior to running the deployment process. The VxRail Deployment Wizard cannot dynamically generate or inject new LAG configurations into an existing, externally managed VDS. During automated initialization, the VxRail Manager discovers these predefined LAG uplinks and maps the designated physical network interface cards (pNICs) of the incoming VxRail nodes to them. This ensures that high-bandwidth traffic such as vSAN and vMotion matches the upstream physical switch configurations immediately upon node discovery and initialization.
