### NEW QUESTION # 76

A user receives an error after attempting to run an extract refresh on the Tableau Server. What should you review to identify the cause of the problem?

- A. The UNC path to the extract's data source
- B. Whether the project permissions are set to Locked to the project
- C. The Background Tasks for Extracts administrative view on the site status page
- D. The status of the Backgrounder process, as shown by the tsm status -v command

**Answer: C**

Explanation:

When an extract refresh fails on Tableau Server, troubleshooting requires identifying the root cause-e.g., connectivity issues, resource constraints, or configuration errors. The Backgrounder process handles extract refreshes, so it's a key focus, but the best diagnostic tool depends on granularity and context. Let's explore this thoroughly:

\* Extract Refresh Process:

\* An extract refresh pulls data from a source (e.g., database, file) into a .hyper file stored on Tableau Server.

- \* The Backgrounder executes these tasks based on schedules or manual triggers.
- \* Errors could stem from: database connectivity, credentials, file access, resource overload, or task misconfiguration.
- \* Option B (Background Tasks for Extracts administrative view): Correct. This is the most direct and detailed method:
- \* Location: In the Tableau Server web UI, go to Server > Status > Background Tasks for Extracts (or site-specific under Site > Status).
- \* Details Provided:
  - \* Task name, schedule, and workbook/data source.
  - \* Start/end times and status (e.g., Failed, Success).
  - \* Error messages (e.g., "Cannot connect to database," "Permission denied").
- \* Why It's Best: It pinpoints the exact failure (e.g., "timeout," "invalid credentials") for the specific refresh, offering actionable insights without needing to dig through logs manually. Server or site administrators can access this view to diagnose issues quickly.
- \* Example: If the error is "Database login failed," you'd check credentials in the data source settings next.
- \* Option A (Status of the Backgrounder process via tsm status -v): Partially useful but insufficient:
  - \* What It Shows: Running/stopped status of all processes (e.g., "Backgrounder: RUNNING").
  - \* Limitation: It confirms if Backgrounder is operational but doesn't reveal why a specific task failed-no error details or task-level granularity.
- \* Use Case: If Backgrounder is stopped or crashed, this might indicate a broader issue, but the question implies a single refresh error, not a server-wide failure.
- \* Option C (The UNC path to the extract's data source): Relevant but secondary:
  - \* Context: If the data source is a file (e.g., CSV on a network share), the UNC path (e.g., \\server\share\file.csv) must be accessible.
  - \* Why Not First: The error could be unrelated (e.g., database issue, not file-based). The admin view (B) would reveal if it's a path issue first, guiding you to check the UNC path only if indicated (e.g., "File not found").
  - \* Practical Note: Backgrounder needs share permissions and the Run As account must access it- checking this without context wastes time.
- \* Option D (Whether project permissions are set to Locked): Unlikely cause:
  - \* Permissions Impact: Locked permissions restrict who can edit/view content, not whether an extract refresh runs-that's tied to the data source's connection settings and Backgrounder execution.
  - \* Exception: If the refresh user lacks "Connect" permission to the data source, it might fail, but this is rare (owner/schedule typically has access). The admin view would flag this.

Why This Matters: The Background Tasks view is Tableau's purpose-built tool for extract diagnostics, saving time and reducing guesswork in production environments.

## NEW QUESTION # 77

Which two statements are advantages of published data sources in comparison to embedded data sources?  
(Choose two.)

- A. Drivers are automatically installed on each client's machine
- B. Data is protected so that it is only available in one workbook
- C. **Centralized data management is easier**
- D. **Storage space is conserved and resource usage during data refreshes is optimized**

**Answer: C,D**

Explanation:

In Tableau, data sources can be embedded (stored within a workbook) or published (stored separately on Tableau Server). Let's define these and analyze the advantages:

- \* Embedded Data Source: The connection details and any extract are bundled in the .twb or .twbx file. Each workbook manages its own copy.
- \* Published Data Source: The connection or extract is hosted on Tableau Server, reusable across multiple workbooks.

Now, let's evaluate the options:

- \* Option C (Centralized data management is easier): Correct. Published data sources allow:
- \* Single source of truth: One data source can serve multiple workbooks, ensuring consistency.
- \* Unified updates: Refresh schedules, permissions, and metadata (e.g., calculated fields) are managed in one place via the Server UI.
- \* Governance: Administrators can control access and monitor usage centrally. In contrast, embedded data sources require individual updates per workbook, leading to duplication and management overhead.
- \* Option D (Storage space is conserved and resource usage during data refreshes is optimized): Correct. With published data sources:
- \* Storage: A single extract on the Server (e.g., a .hyper file) is shared across workbooks, avoiding redundant copies stored in each embedded workbook.

\* Refreshes: One refresh job updates the shared extract, reducing CPU and memory usage compared to multiple refreshes for duplicate embedded extracts. Embedded data sources replicate extracts, increasing disk space and refresh load.

\* Option A (Data is protected so that it is only available in one workbook): Incorrect. This describes embedded data sources, not published ones. Published data sources are shared, not restricted to one workbook-permissions control access, not exclusivity.

\* Option B (Drivers are automatically installed on each client's machine): Incorrect. Drivers (e.g., for SQL Server, PostgreSQL) must be installed on the Server hosting the published data source, not client machines. This is unrelated to the published vs. embedded distinction.

Why This Matters: Published data sources enhance scalability and efficiency in enterprise deployments, making them a cornerstone of Tableau Server's data strategy.
