XSIAM-Engineer Latest Dumps, Test XSIAM-Engineer Book

The accuracy rate of XSIAM-Engineer test training materials of PassSureExam is high with wide coverage. It will be the most suitable XSIAM-Engineer test training materials and the one you need most to pass XSIAM-Engineer exam. We promise that we will provide renewal service freely as long as one year after you purchase our XSIAM-Engineer Dumps; if you fail XSIAM-Engineer test or there are any quality problem of our XSIAM-Engineer exam dumps and training materials, we will give a full refund immediately.

Palo Alto Networks XSIAM Engineer Sample Questions (Q194-Q199):

NEW QUESTION # 194

Which two requirements must be met for a Cortex XDR agent to successfully use the Broker VM as a download source for content updates? (Choose two.)

- A. Broker VM must be configured with an FQDN.
- B. Device Configuration profile applied to the XDR agent must specify the Broker VM as a Download Source.
- C. Agent Settings profile applied to the XDR agent must specify the Broker VM as a Download Source.
- D. XDR agent must authenticate to the Broker VM using a machine certificate.\

Answer: A,C

Explanation:

For Cortex XDR agents to use the Broker VM as a download source, the Agent Settings profile must specify the Broker VM as the update source, and the Broker VM must be configured with an FQDN so agents can reliably resolve and connect to it.

NEW QUESTION # 195

A critical XSIAM dashboard relies on data from a custom application data source. Users report that recent data points on the dashboard are inconsistent, showing sudden drops or spikes that don't align with the application's behavior. Upon inspecting the raw logs in XSIAM for the affected period, it's observed that a non-standard value, 'N/A', is appearing in a numeric field ('transaction_value') which should only contain decimal numbers. This 'N/A' is causing downstream aggregations to fail or return incorrect results. What is the most robust way to handle this data quality issue within XSIAM's ingestion pipeline?

- A. Change the schema of the 'transaction_value' field from 'number' to 'string' in XSIAM. This would allow 'N/A' but prevent numeric operations.
- B. Contact the application development team to ensure they stop sending 'N/A' in numeric fields. This is the ideal long-term solution but doesn't fix existing or immediate data.
- C. Implement a 'mutate or 'replace' operation within the XSIAM parsing rule or a post-parsing normalization step to convert 'N/A' to 'null' or for the 'transaction_value' field, ensuring it's treated as a numeric type. This needs to occur before indexing.
- D. Modify the XSIAM query used by the dashboard to filter out events where 'transaction_value' is 'N/A'. This addresses the dashboard view but not the underlying data quality in the index.
- E. Scale up the XSIAM Data Lake nodes to improve indexing performance, which might implicitly fix data type issues. This is unrelated to data content validation.

Answer: C

Explanation:

This scenario describes a data quality issue where non-numeric values are entering a numeric field, breaking aggregations. The most robust way to handle this in the ingestion pipeline is to 'cleanse' the data during parsing or normalization. Option B is the correct approach: using XSIAM's built-in processing capabilities (like 'mutate' or 'replace' operations) to transform 'N/A' into a value that is compatible with the numeric field type (e.g., 'null' or '0') before the data is indexed. Option A only hides the problem. Option C is a long-term goal but not an immediate fix. Option D compromises data utility. Option E is irrelevant.

NEW QUESTION # 196

A financial institution is evaluating XSIAM for its security operations. A key requirement is the ability to enrich XSIAM alerts with proprietary threat intelligence feeds hosted internally on a custom API endpoint that requires specific authentication headers. Which XSIAM capability or integration approach is best suited for incorporating this custom threat intelligence into alert enrichment?

- A. Develop a custom playbook action within XSIAM's orchestration capabilities that can make authenticated API calls to the internal threat intelligence platform.
- B. Leverage XSIAM's built-in third-party threat intelligence integrations for generic API endpoints.
- C. Export the custom threat intelligence as a CSV file daily and manually upload it to XSIAM as a lookup list.
- D. Configure a custom data source using the XSIAM Data Collector to periodically pull data from the API and ingest it as raw logs.
- E. Use a native XSIAM integration module designed for standard STIX/TAXII feeds.

Answer: A

Explanation:

For custom API endpoints requiring specific authentication headers, developing a custom playbook action (Option A) within XSIAM is the most effective approach. This allows dynamic queries to the internal TI platform during alert enrichment, providing context on demand. Option A is for standard feeds. Option B would ingest the TI as logs, not necessarily for direct alert enrichment. Option D is manual and not real-time. Option E is too generic and may not support custom authentication.

NEW QUESTION # 197

Consider a complex XSIAM deployment where user authentication is managed via an external Identity Provider (IdP) using SAML. A new requirement emerges: certain XSIAM-internal automation scripts, running as service accounts, need to programmatically interact with XSIAM to ingest data and manage incidents, without relying on IdP-based authentication. Which of the following is the most secure and recommended approach for authenticating these service accounts to XSIAM?

- A. Configure the IdP to issue specific tokens for service accounts that can be directly consumed by XSIAM, bypassing SAML for human users.
- B. Create dedicated local XSIAM user accounts for each service script and store their credentials securely in a secrets manager, then use basic authentication via the XSIAM API.
- C. Utilize XSIAM's 'Guest User' feature for service accounts, as it provides a simplified authentication mechanism for automated processes.
- D. Implement an OAuth 2.0 flow where XSIAM acts as the authorization server and the service scripts are confidential clients.
- E. Generate API keys or tokens directly within XSIAM for each service account, ensuring these tokens have specific, limited permissions, and store them securely.

Answer: E

Explanation:

For programmatic access and service accounts, XSIAM strongly recommends using API keys or tokens. These can be generated within XSIAM, assigned specific roles and permissions (principle of least privilege), and revoked easily. This provides a secure, auditable, and manageable way for automation to interact with XSIAM without relying on human-centric authentication methods like IdP SAML flows. Option A, while possible, relies on managing username/password pairs, which is generally less secure than API keys. Option C is less practical as IdPs are typically for human user authentication. Option D (Guest User) is not designed for service account automation. Option E (OAuth 2.0) is a complex solution typically used for delegated authorization between services, not direct API access for an internal script to a single application.

NEW QUESTION # 198

An XSOAR playbook that relies on an external XSIAM API call (using the 'xsiam-api-v2-post-incidents-enrichment' command) is intermittently failing with a '429 Too Many Requests' error. The playbook is designed to enrich incidents as they occur. What is the most robust long-term solution to mitigate this rate-limiting issue without significantly impacting the enrichment process?

- A. Increase the 'requests.timeout' parameter in the API call to allow more time for the server to respond.
- B. Reduce the frequency of incident generation in XSIAM to lower the load on the enrichment playbook.
- C. Implement a retry mechanism with exponential backoff for the 'xsiam-api-v2-post-incidents-enrichment' command within the playbook.
- D. Configure a dedicated XSOAR engine specifically for the incident enrichment playbook to improve performance.
- E. Switch to a different XSIAM API endpoint that has higher rate limits.

Answer: C

Explanation:

A '429 Too Many Requests' error explicitly indicates rate limiting. The most robust long-term solution for intermittent rate limiting is to implement a retry mechanism with exponential backoff (B). This allows the playbook to automatically re-attempt the API call after increasing delays, giving the API time to reset its rate limits. Option A is for connection timeouts, not rate limits. Option C is not a practical solution for operational security. Option D might improve overall playbook execution speed but won't inherently solve rate limiting by an external API. Option E is highly unlikely to be feasible or available.

NEW QUESTION # 199

.....

When it comes to XSIAM-Engineer exam, many candidates are lack of confidence to pass it. But we all know self-confidence is the spiritual pillar of a person as well as the inherent power, which is of great importance and value to a person who want to pass the XSIAM-Engineer exam.
