CheckPoint Check Point Certified Troubleshooting Expert - R81.20 Sample Questions (Q11-Q16):

NEW QUESTION # 11

PostgreSQL is a powerful, open source relational database management system. Check Point offers a command for viewing the database to interact with Postgres interactive shell. Which command do you need to enter the PostgreSQL interactive shell?

- A. `mysql -u root`
- B. `mysql_client cpm postgres`
- C. `psql_client cpm postgres`
- D. `psql_client postgres cpm`

Answer: C

Explanation:

The correct command to enter the PostgreSQL interactive shell is `psql_client cpm postgres`. This command allows the administrator to view and manipulate the database of the Check Point Management (CPM) module, which stores the configuration and policy data. The `psql_client` command is a Check Point wrapper for the `psql` command, which is the native PostgreSQL interactive shell. The `psql_client` command takes two arguments: the first one is the name of the database module, and the second one is the name of the database user. In this case, the database module is `cpm` and the database user is `postgres`.

The other commands are incorrect because:

- A. `mysql_client cpm postgres` is not a valid command. The `mysql_client` command is used to access the MySQL database, which is not used by Check Point. The Check Point database is based on PostgreSQL, not MySQL.
- B. `mysql -u root` is not a valid command. The `mysql` command is used to access the MySQL database, which is not used by Check Point. The Check Point database is based on PostgreSQL, not MySQL. Moreover, the `-u` option specifies the MySQL user name, which is not relevant for Check Point.
- D. `psql_client postgres cpm` is not a valid command. The `psql_client` command takes the database module name as the first

argument, and the database user name as the second argument. In this case, the database module name is cpm and the database user name is postgres. The order of the arguments is reversed in this command.

NEW QUESTION # 12

If the cpsemd process of SmartEvent has crashed or is having trouble coming up, then it usually indicates that _____.

- A. The logged in administrator does not have permissions to run SmartEvent
- B. The SmartEvent core on the Solr indexer has been deleted
- C. Cpd daemon is unable to connect to the log server
- D. Postgres database is down

Answer: D

Explanation:

cpsemd is the process responsible for logging into the SmartEvent GUI. Therefore, you need to check the status of this process and debug it, if necessary. Usually, the issue with the cpsemd process is that it is crashing, or not coming up. What causes this process to crash or not come up is that the PostgreSQL database is down. Therefore, in order to run the cpsemd process successfully, you need to run the PostgreSQL database successfully.

NEW QUESTION # 13

When URL category is not found in the kernel cache, what action will GW do?

- A. GW will update kernel cache during next policy install
- B. RAD forwards this request to CMI which is the brain of inspection
- C. RAD in kernel space will forward request to the cloud
- D. RAD In user space will forward request to the cloud

Answer: D

NEW QUESTION # 14

When a User Mode process suddenly crashes, it may create a core dump file. Which of the following information is available in the core dump and may be used to identify the root cause of the crash?

- Program Counter
- Stack Pointer
- Memory management information
- Other Processor and OS flags / information

- A. iii and iv only
- B. Only lii
- C. i, ii, iii and iv
- D. i and ii only

Answer: C

Explanation:

A core dump file is essentially a snapshot of the process's memory at the time of the crash. This snapshot includes crucial information that can help diagnose the cause of the crash. Here's why all the options are relevant:

- Program Counter:** This register stores the address of the next instruction the CPU was supposed to execute. It pinpoints exactly where in the code the crash occurred.
- Stack Pointer:** This register points to the top of the call stack, which shows the sequence of function calls that led to the crash. This helps trace the program's execution flow before the crash.
- Memory management information:** This includes details about the process's memory allocations, which can reveal issues like memory leaks or invalid memory access attempts.
- Other Processor and OS flags/information:** This encompasses various registers and system information that provide context about

the state of the processor and operating system at the time of the crash.

By analyzing this information within the core dump, you can often identify the root cause of the crash, such as a segmentation fault, null pointer dereference, or stack overflow.

Check Point Troubleshooting Reference:

While core dumps are a general concept in operating systems, Check Point's documentation touches upon them in the context of troubleshooting specific processes like fwd (firewall) or cpd (Check Point daemon). The fw ctl zdebug command, for example, can be used to trigger a core dump of the fwd process for debugging purposes.
