NEW QUESTION # 477

The optimal, sequential order in which cloud resources should be recovered in the event of a major failure would be defined in the:

- A. recovery point objective.
- B. network topology diagram.
- **C. disaster recovery plan.**
- D. incident response plan.

Answer: C

NEW QUESTION # 478

Which of the following are aspects of cloud data availability? (Choose two.)

- A. Auto-scaling
- B. Resource tagging
- C. Locality
- **D. Zones**

- E. Data sovereignty
- F. Geo-redundancy

Answer: D,F

Explanation:

Cloud data availability is the process of ensuring that data is accessible to end users and applications, when and where they need it. It defines the degree or extent to which data is readily usable along with the necessary IT and management procedures, tools and technologies required to enable, manage and continue to make data available¹. Cloud data availability is influenced by several aspects, such as:

Zones: Zones are logical or physical partitions of a cloud region that have independent power, cooling, and networking infrastructure. They are designed to isolate failures within a region and provide high availability and fault tolerance for cloud services and data. For example, Google Cloud² and Azure³ offer availability zones that allow users to distribute their resources and data across multiple zones within a region, ensuring that if one zone experiences an outage, the other zones can continue to function and serve the data.

Geo-redundancy: Geo-redundancy is the practice of replicating or storing data across multiple geographic locations or regions. It is intended to improve data availability and durability by protecting data from regional disasters, network failures, or malicious attacks. For example, Google Cloud² and Azure³ offer geo-redundant storage options that allow users to store their data in two or more regions, ensuring that if one region becomes unavailable, the data can be accessed from another region.

Resource tagging is the practice of assigning metadata or labels to cloud resources, such as instances, volumes, or buckets. It is used to organize, manage, and monitor cloud resources and data, but it does not directly affect data availability.

Data sovereignty is the concept that data is subject to the laws and regulations of the country or region where it is stored or processed. It is a legal and compliance issue that affects data security, privacy, and governance, but it does not directly affect data availability.

Locality is the concept that data is stored or processed close to the source or destination of the data. It is used to optimize data performance, latency, and bandwidth, but it does not directly affect data availability.

Auto-scaling is the practice of automatically adjusting the amount or type of cloud resources, such as instances, nodes, or pods, based on the demand or load of the data. It is used to optimize data efficiency, scalability, and reliability, but it does not directly affect data availability. Reference:

NEW QUESTION # 479

Privacy is the right of _____ to selectively disclose information about _____ and restrict the further use of that information by any party.

- A. individuals, themselves
- B. companies, others
- C. individuals, others
- D. companies, themselves

Answer: A

NEW QUESTION # 480

A company migrated all of its infrastructure to the cloud. The cloud security team must review the security post-migration. Which of the following is the MOST appropriate task for the cloud security team to perform?

- A. Risk register
- B. Threat assessment
- C. Application scan
- D. Vulnerability scan

Answer: D

Explanation:

A vulnerability scan is a process of identifying and reporting potential security weaknesses in a system or network. A vulnerability scan can help detect misconfigurations, outdated software, missing patches, and other issues that could compromise the security of the cloud environment. A vulnerability scan is an appropriate task for the cloud security team to perform after migrating the

infrastructure to the cloud, as it can help identify and remediate any security gaps that may have occurred during the migration process. A vulnerability scan can also help the cloud security team comply with the security standards and regulations that apply to the cloud service provider and the cloud customer.

A risk register is a document that lists the identified risks, their likelihood, impact, and mitigation strategies for a project or organization. A risk register is not a post-migration task, but rather a pre-migration task that should be created and updated throughout the cloud migration process. A risk register can help the cloud security team assess and manage the risks associated with the cloud migration, and plan for contingencies and backups in case of any unforeseen events.

A threat assessment is a process of identifying and analyzing the potential threats that could harm a system or network. A threat assessment can help the cloud security team determine the sources, motives, capabilities, and methods of the attackers, and prioritize the most critical and likely threats. A threat assessment is not a post-migration task, but rather a continuous task that should be performed regularly to monitor and respond to the evolving threat landscape. A threat assessment can help the cloud security team enhance the security posture and resilience of the cloud environment, and implement appropriate countermeasures and controls.

An application scan is a process of testing and verifying the functionality and security of an application. An application scan can help detect and report any errors, bugs, vulnerabilities, or performance issues in an application. An application scan is not a post-migration task, but rather a development and deployment task that should be performed before and after launching an application in the cloud. An application scan can help the cloud security team ensure the quality and reliability of the application, and fix any issues that could affect the user experience or security of the application.
