CVSS exploitability score 10.0

availability Impact PARTIAL

After a cyber attack, an engineer is analyzing an alert that was missed on the intrusion detection system. The attack exploited a vulnerability in a business-critical, web-based application and violated its availability. Which two mitigation techniques should the engineer recommend? (Choose two.)

- A. NOP sled technique
- B. data execution prevention
- C. address space randomization
- D. encapsulation
- E. heap-based security

Answer: B,C

Explanation:

The alert indicates a WebDAV Stack Buffer Overflow, which is a memory corruption attack targeting the stack, a common vector for remote code execution or denial-of-service (DoS).

To mitigate such exploits, two effective system-hardening techniques are:

* C. Address Space Layout Randomization (ASLR): Randomizes memory addresses used by system and application processes, making it difficult for attackers to predict where their malicious code will be executed.

* E. Data Execution Prevention (DEP): Prevents execution of code from non-executable memory regions such as the stack, thus stopping buffer overflow attacks from successfully executing payloads.

Both are well-established protections against stack-based buffer overflow attacks and are strongly recommended in the Cisco CyberOps Associate guide and general security best practices.
